Topics

- Optimality
- Value function iteration (VFI)
- Howard policy iteration (OPI)
- Optimistic policy iteration (HPI)

What convergence properties?

How do they interact with parallelization?

Set Up

We take as given

- 1. a set X with n elements called the **state space** and
- 2. a finite set A called the action space

We study an agent who, at each integer $t \geqslant 0$

- 1. observes the current state $X_t \in X$
- 2. responds with an action $A_t \in A$

Her aim is to maximize

$$\mathbb{E}\sum_{t\geq 0}\beta^t r(X_t, A_t) \quad \text{ given } X_0 = x_0$$

Let P denote transition probabilities:

$$P(x, a, x') = \text{ prob of transitioning to } x' \text{ given } x, a$$

The Bellman equation is

$$v(x) = \max_{a \in \Gamma(x)} \left\{ r(x, a) + \beta \sum_{x' \in \mathsf{X}} v(x') P(x, a, x') \right\}$$

• $\Gamma(x) =$ actions available in state x

Policies

A feasible policy is a map σ from X to A such that

$$\sigma(x) \in \Gamma(x)$$
 for all $x \in X$

• Let $\Sigma :=$ the set of all feasible policies

Choosing
$$\sigma \in \Sigma \implies$$

respond to state X_t with action $A_t := \sigma(X_t)$ at $\underline{\mathsf{all}}\ t \geqslant 0$

Fixing $\sigma \in \Sigma$, set

- $P_{\sigma}(x,x') := P(x,\sigma(x),x') = \text{Markov dynamics given } \sigma$
- $r_{\sigma}(x) := r(x, \sigma(x)) = \text{rewards at } x \text{ given } \sigma$
- $\mathbb{E}_x := \mathbb{E}[\cdot \mid X_0 = x]$

When our actions follow σ , we have

$$\mathbb{E}_x r(X_t, A_t) = \mathbb{E}_x r_{\sigma}(X_t) = \sum_{x'} r_{\sigma}(x') P_{\sigma}^t(x, x') = (P_{\sigma}^t r_{\sigma})(x)$$

The **lifetime value of** σ starting from x is

$$v_{\sigma}(x) := \mathbb{E}_{x} \sum_{t \geqslant 0} \beta^{t} r_{\sigma}(X_{t})$$
$$= \sum_{t \geqslant 0} \mathbb{E}_{x} \left[\beta^{t} r_{\sigma}(X_{t}) \right]$$
$$= \sum_{t \geqslant 0} \beta^{t} (P_{\sigma}^{t} r_{\sigma})(x)$$

By the Neumann (geometric) series lemma,

$$v_{\sigma} = \sum_{t>0} (\beta P_{\sigma})^t r_{\sigma} = (I - \beta P_{\sigma})^{-1} r_{\sigma}$$

Policy Operators

The **policy operator** corresponding to σ is

$$(T_{\sigma} v)(x) = r(x, \sigma(x)) + \beta \sum_{x' \in \mathsf{X}} v(x') P(x, \sigma(x), x')$$

In vector notation (with $v \in \mathbb{R}^n$),

$$T_{\sigma} v = r_{\sigma} + \beta P_{\sigma} v$$

• Fact. T_{σ} is a contraction map on \mathbb{R}^n

Fact. v_{σ} is the unique fixed point of T_{σ} in \mathbb{R}^n

Proof: Since $\beta < 1$, we have

$$v = T_{\sigma} v \iff v = r_{\sigma} + \beta P_{\sigma} v$$
 $\iff v = (I - \beta P_{\sigma})^{-1} r_{\sigma}$
 $\iff v = v_{\sigma}$

Hence

v is a fixed point of $T_{\sigma} \iff v = v_{\sigma}$

Fact. v_{σ} is the unique fixed point of T_{σ} in \mathbb{R}^n

Proof: Since $\beta < 1$, we have

$$v = T_{\sigma} v \iff v = r_{\sigma} + \beta P_{\sigma} v$$

$$\iff v = (I - \beta P_{\sigma})^{-1} r_{\sigma}$$

$$\iff v = v_{\sigma}$$

Hence

v is a fixed point of $T_{\sigma} \iff v = v_{\sigma}$

Greedy Policies

Fix $v \in \mathbb{R}^n$

A policy σ is called v-greedy if

$$\sigma(x) \in \operatorname*{argmax}_{a \in \Gamma(x)} \left\{ r(x, a) + \beta \sum_{x'} v(x') P(x, a, x') \right\}$$

for all $x \in X$

Ex. Prove: at least one v-greedy policy exists in Σ

The **Bellman operator** is defined by

$$(Tv)(x) = \max_{a \in \Gamma(x)} \left\{ r(x, a) + \beta \sum_{x'} v(x') P(x, a, x') \right\}$$

By construction,

 $Tv = v \iff v$ satisfies the Bellman equation

Optimality

The value function is defined by

$$v^*(x) := \max_{\sigma \in \Sigma} v_{\sigma}(x) \qquad (x \in \mathsf{X})$$

A policy $\sigma \in \Sigma$ is called **optimal** if

$$v_{\sigma} = v^*$$

Standard theory (Bellman, Denardo, Blackwell)

Theorem. For the DP model described above,

- 1. v^* is the unique fixed point of T in \mathbb{R}^n
- 2. A feasible policy is optimal if and only it is v^* -greedy
- 3. At least one optimal policy exists

Algorithms

- 1. Value function iteration (HPI)
- 2. Howard policy iteration (HPI)
- 3. Optimistic policy iteration (OPI)

Algorithm 1: VFI for MDPs

```
\begin{split} & \text{input } v_0 \in \mathbb{R}^n \\ & \text{input } \tau \\ & \varepsilon \leftarrow \tau + 1 \\ & k \leftarrow 0 \\ & \text{while } \varepsilon > \tau \text{ do} \\ & & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & \\ & & & \\ & & \\ & & & \\ & & \\ & & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\
```

end

Compute a v_k -greedy policy σ

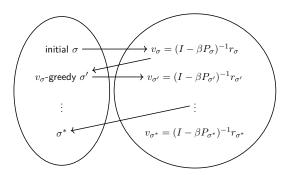

return σ

VFI is

- easy to understand
- easy to implement
- globally convergent

But the convergence rate is only linear

Howard Policy Iteration

Iterates between computing the value of a given policy and computing the greedy policy associated with that value

Algorithm 2: Howard policy iteration for MDPs

```
\begin{array}{l} \text{input } \sigma \in \Sigma \\ v_0 \leftarrow v_\sigma \text{ and } k \leftarrow 0 \\ \text{repeat} \\ \mid \sigma_k \leftarrow \text{a } v_k\text{-greedy} \\ v_{k+1} \leftarrow (I - \beta P_\sigma) \end{array}
```

$$\begin{array}{l} \sigma_k \leftarrow \text{a} \ v_k\text{-greedy policy} \\ v_{k+1} \leftarrow (I-\beta P_{\sigma_k})^{-1} r_{\sigma_k} \\ \text{if} \ v_{k+1} = v_k \ \text{then} \ \text{break} \\ k \leftarrow k+1 \end{array}$$

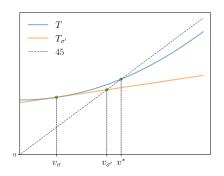

return σ_k

Proposition. HPI returns an exact optimal policy in a finite number of steps

Also, rate of convergence is faster than VFI

In fact HPI = gradient-based Newton iteration on T

- Implies a quadratic rate of convergence
- Details are in https://dp.quantecon.org

- σ' is v_{σ} -greedy if $T_{\sigma'}v_{\sigma}=Tv_{\sigma}$
- $v_{\sigma'}$ is the fixed point of $T_{\sigma'}$

Optimistic Policy Iteration

OPI is a "convex combination" of VFI and HPI

Similar to HPI except that

- HPI takes current σ and obtains v_{σ}
- ullet OPI takes current σ and iterates m times with T_{σ}

Recall that, for any $v \in \mathbb{R}^n$, we have $T_\sigma^m v \to v_\sigma$ as $m \to \infty$

Hence OPI replaces v_{σ} with an approximation

Algorithm 3: Optimistic policy iteration for MDPs

```
input v_0 \in \mathbb{R}^n
input 	au
input m \in \mathbb{N}, a step size
k \leftarrow 0
\varepsilon \leftarrow \tau + 1
while \varepsilon > \tau do
       \sigma_k \leftarrow a \ v_k-greedy policy
  v_{k+1} \leftarrow T_{\sigma_k}^m v_k
\varepsilon \leftarrow \|v_k - v_{k+1}\|_{\infty}
k \leftarrow k+1
end
```

return σ_k

Proposition. For all values of m we have $v_k \to v^*$

It's easy to show that ${\sf OPI}={\sf VFI}$ when m=1 On the other hand, m is large, ${\sf OPI}$ is similar to HPI

• because $\lim_{m\to\infty} T^m_{\sigma_k} v_k = v_{\sigma_k}$

Rules of thumb:

- parallelization favors HPI small number of expensive steps
- ullet OFI is simple and dominates VFI for many values of m
- VFI works well when β is small and optimization is cheap
